5.1 Introduction to Push Down Automata (PDA), Representation of PDA, Operations of PDA, Move of a PDA, Instantaneous Description for PDA

5.2 Deterministic PDA, Non Deterministic PDA, Acceptance of strings by PDA, Language of PDA

5.3 Construction of PDA by Final State , Construction of PDA by Empty Stack,

5.4 Conversion of PDA by Final State to PDA accepting by Empty Stack and vice-versa, Conversion of CFG to PDA, Conversion of PDA to CFG

# Pushdown Automata

- ◆ The PDA is an automaton equivalent to the CFG in language-defining power.
- ◆ Only the nondeterministic PDA defines all the CFL's.
- ◆ But the deterministic version models parsers.
  - ◆ Most programming languages have deterministic PDA's.

# Introduction: PDA

- ◆ The PDA is a Abstract Machine which is considered to have input tape, finite control and a Stack.
- ◆ Its moves are determined by:
  1. The current state.
  2. The current input symbol (or  $\epsilon$ ), and
  3. The current symbol on top of its stack.

# Introduction: PDA

- ◆ Being a nondeterministic, the PDA can have a choice of next moves.
- ◆ At each step, PDA can have either push or pop operation in its stack.
- ◆ In each choice, the PDA can:
  1. Change state, and also
  2. Replace the top symbol on the stack by a sequence of zero or more symbols.
    - ◆ Zero symbols = "pop."
    - ◆ Many symbols = sequence of "pushes."

# PDA – Formal Definition

- ◆ A PDA is described by 7 tuples as
  - ◆  $P = (Q, \Sigma, \Gamma, \delta, q_0, Z_0, F)$  where :
    1.  $Q$  = A finite set of *states*
    2.  $\Sigma$  = An *input alphabet*
    3.  $\Gamma$  = A *stack alphabet*
    4.  $\delta$  = A *transition function*
    5.  $q_0$  = A *start state* ( $q_0$ , in  $Q$ ).
    6.  $Z_0$  = A *start symbol* ( $Z_0$ , in  $\Gamma$ , typically).
    7.  $F$  = A set of *final states* ( $F \subseteq Q$ , typically).

# Conventions

- ◆  $a, b, \dots$  are input symbols.
  - ◆ But sometimes we allow  $\epsilon$  as a possible value.
- ◆  $\dots, X, Y, Z$  are stack symbols.
- ◆  $\dots, w, x, y, z$  are strings of input symbols.
- ◆  $\alpha, \beta, \dots$  are strings of stack symbols.

# The Transition Function

- ◆ Takes three arguments:
  1. A state, in  $Q$ .
  2. An input, which is either a symbol in  $\Sigma$  or  $\epsilon$ .
  3. A stack symbol in  $\Gamma$ .
- ◆  $\delta(q, a, Z)$  is a set of zero or more actions of the form  $(p, \alpha)$ .
  - ◆  $p$  is a state;  $\alpha$  is a string of stack symbols.

# Actions of the PDA

- ◆ If  $\delta(q, a, Z)$  contains  $(p, \alpha)$  among its actions, then one thing the PDA can do in state  $q$ , with  $a$  at the front of the input, and  $Z$  on top of the stack is:
  1. Change the state to  $p$ .
  2. Remove  $a$  from the front of the input (but  $a$  may be  $\epsilon$ ).
  3. Replace  $Z$  on the top of the stack by  $\alpha$ .

## Example: PDA

- ◆ Design a PDA to accept  $\{0^n 1^n \mid n \geq 1\}$ .
- ◆ The states:
  - ◆  $q$  = start state. We are in state  $q$  if we have seen only 0's so far.
  - ◆  $p$  = we've seen at least one 1 and may now proceed only if the inputs are 1's.
  - ◆  $f$  = final state; accept.

## Example: PDA – (contd..)

### ◆ The stack symbols:

- ◆  $Z_0$  = start symbol. Also marks the bottom of the stack, so we know when we have counted the same number of 1's as 0's.
- ◆  $X$  = marker, used to count the number of 0's seen on the input.

## Example: PDA – (3)

### ◆ The transitions:

- ◆  $\delta(q, 0, Z_0) = \{(q, XZ_0)\}$ .
- ◆  $\delta(q, 0, X) = \{(q, XX)\}$ . These two rules cause one  $X$  to be pushed onto the stack for each  $0$  read from the input.
- ◆  $\delta(q, 1, X) = \{(p, \epsilon)\}$ . When we see a  $1$ , go to state  $p$  and pop one  $X$ .
- ◆  $\delta(p, 1, X) = \{(p, \epsilon)\}$ . Pop one  $X$  per  $1$ .
- ◆  $\delta(p, \epsilon, Z_0) = \{(f, Z_0)\}$ . Accept at bottom.

# Instantaneous Descriptions

- ◆ We can formalize the pictures just seen with an *instantaneous description* (ID).
- ◆ The current configuration of a PDA at any instance is described by triplate which is called ID of PDA
- ◆ A ID is a triple  $(q, w, \alpha)$ , where:
  1.  $q$  is the current state.
  2.  $w$  is the remaining input.
  3.  $\alpha$  is the stack contents, top at the left.

# The “Goes-To” Relation

- ◆ To say that ID I can become ID J in one move of the PDA, we write  $I \vdash J$ .
- ◆ Formally,  $(q, aw, X\alpha) \vdash (p, w, \beta\alpha)$  for any  $w$  and  $\alpha$ , if  $\delta(q, a, X)$  contains  $(p, \beta)$ .
- ◆ Extend  $\vdash$  to  $\vdash^*$ , meaning “zero or more moves,” by:
  - ◆ **Basis:**  $I \vdash^* I$ .
  - ◆ **Induction:** If  $I \vdash^* J$  and  $J \vdash K$ , then  $I \vdash^* K$ .

## Example: Goes-To

- ◆ Using the previous example PDA, we can describe the sequence of moves by:  
 $(q, 000111, Z_0) \vdash (q, 00111, XZ_0) \vdash$   
 $(q, 0111, XXZ_0) \vdash (q, 111, XXXZ_0) \vdash$   
 $(p, 11, XXZ_0) \vdash (p, 1, XZ_0) \vdash (p, \epsilon, Z_0) \vdash$   
 $(f, \epsilon, Z_0)$
- ◆ Thus,  $(q, 000111, Z_0) \vdash^* (f, \epsilon, Z_0)$ .
- ◆ What would happen on input 0001111?

# Answer

Legal because a PDA can use  $\epsilon$  input even if input remains.

- ◆  $(q, 0001111, Z_0) \vdash (q, 001111, XZ_0) \vdash (q, 01111, XXZ_0) \vdash (q, 1111, XXXZ_0) \vdash (p, 111, XXZ_0) \vdash (p, 11, XZ_0) \vdash (p, 1, Z_0) \vdash (f, 1, Z_0)$
- ◆ Note the last ID has no move.
- ◆ 0001111 is **not** accepted, because the input is not completely consumed.

# Language of a PDA

- ◆ The common way to define the language of a PDA is by *final state*.
- ◆ If  $P$  is a PDA, then  $L(P)$  is the set of strings  $w$  such that  $(q_0, w, Z_0) \vdash^* (f, \epsilon, \alpha)$  for final state  $f$  and any  $\alpha$ .

## Language of a PDA – (2)

- ◆ Another language defined by the same PDA is by *empty stack*.
- ◆ If  $P$  is a PDA, then  $N(P)$  is the set of strings  $w$  such that  $(q_0, w, Z_0) \vdash^* (q, \epsilon, \epsilon)$  for any state  $q$ .
- ◆ In this case, the PDA is defined by 6-tuples only where there is no final states.

# PDA from Empty Stack to Final State

- ◆ Given a PDA that accepts by empty stack,  $P_N = (Q, \Sigma, \Gamma, \delta_N, q_0, Z_0)$ .
- ◆ Let  $P_F$  is PDA accepting by Final State.
- ◆ Let  $X_0$  not in  $\Gamma$ , is the start symbol of  $P_F$  and use bottom marker of  $P_N$  after emptying its stack.
- ◆ Define a start state  $p_0$  of  $P_F$ , and from  $p_0$  it pushes  $Z_0$  on the top of stack and enters into  $q_0$ , start state of  $P_N$ .
- ◆ From  $q_0$ , other moves are same for  $P_F$  like  $P_N$
- ◆ When the stack of  $P_N$  becomes empty entering any state  $p$ ,  $P_F$  sees the  $X_0$  on the top of stack.
- ◆ Add another state  $p_f$ , so that from  $p$ ,  $P_F$  moves to  $p_f$  which is final state.

Continue.....

◆ The complete specification of  $P_F$  is :

◆  $P_F = (Q \cup \{p_0, p_f\}, \Gamma \cup \{X_0\}, \delta_F, p_0, X_0, \{p_f\})$  and  $\delta_F$  is defined by,

1.  $\delta_F(p_0, \epsilon, X_0) = \{(q_0, Z_0 X_0)\}$
2. For all state  $q$  in  $Q$ ,  $a$  in  $\Sigma$  or  $a = \epsilon$ , stack symbol  $Y$  in  $\Gamma$ ,  
 $\delta_F(q, a, Y) = \delta_N(q, a, Y)$ .
3.  $\delta_F(q, \epsilon, X_0) = (p_f, \epsilon)$ .

**Simulating empty stack by Final State**

# PDA from Final state to empty Stack

- ◆ Given a PDA that accepts by empty stack,  $P_F = (Q, \Sigma, \Gamma, \delta_F, q_0, Z_0, F)$ . We can construct PDA accepting same language by empty stack as:
  - ◆ Let  $P_N$  is PDA accepting by empty stack.
  - ◆ Let  $X_0$  not in  $\Gamma$ , is the start symbol of  $P_N$  and use bottom marker of  $P_F$ .
  - ◆ Define a start state  $p_0$  of  $P_N$ , and from  $p_0$  it pushes  $Z_0$  on the top of stack and enters into  $q_0$ , start state of  $P_F$  on input  $\epsilon$ .
  - ◆ From  $q_0$ , other moves are same for  $P_N$  like  $P_F$
  - ◆ From each final state of  $P_F$ , add transition on  $\epsilon$  to new state  $p$  and pop from stack.
  - ◆ From state  $p$ , pop each stack symbol until it is empty since this is the situation after consuming input string.
  - ◆ Thus  $P_N$  accepts by empty stack.

Continue.....

◆ The complete specification of  $P_N$  is :

- ◆  $P_N = (Q \cup \{p_0, p\}, \Gamma \cup \{X_0\}, \delta_N, p_0, X_0)$  and  $\delta_N$  is defined by,
  1.  $\delta_N(p_0, \epsilon, X_0) = \{(q_0, Z_0 X_0)\}$
  2. For all state  $q$  in  $Q$ ,  $a$  in  $\Sigma$  or  $a = \epsilon$ , stack symbol  $Y$  in  $\Gamma$ ,  
 $\delta_N(q, a, Y) = \delta_F(q, a, Y)$ .
  3. For all  $q$  in  $F$ ,  $Y$  in  $\Gamma$  or  $Y = X_0$ ,  $\delta_N(q, \epsilon, Y) = (p, \epsilon)$ .
  4. For all  $Y$  in  $\Gamma \cup \{X_0\}$ ,  $\delta_N(p, \epsilon, Y) = (p, \epsilon)$ .

**Simulating Final state PDA by empty stack PDA**

# Deterministic PDA's

- ◆ To be deterministic, there must be at most one choice of move for any state  $q$ , input symbol  $a$ , and stack symbol  $X$ .
- ◆ In addition, there must not be a choice between using input  $\epsilon$  or real input.
- ◆ Formally,  $\delta(q, a, X)$  and  $\delta(q, \epsilon, X)$  cannot both be nonempty.

# Exercise

1. Construct a PDA accepting a language  $L = \{w \mid w \text{ is in } \{a,b\}^* \text{ and } w \text{ has equal no of } a\text{'s and } b\text{'s} \}$
2. Construct a PDA accepting  $L = \{ww^R \mid w \text{ is in } \{0,1\}^*\}$
3. Construct a PDA acceting  $L = \{wcw^R \mid w \text{ is in } \{1,0\}^*\}$
